Background of the Invention

Inosine monophosphate dehydrogenase (IMPDH) has been
shown to be a key enzyme in the regulation of cell
proliferation and differentiation. Nucleotides are
required for cells to divide and replicate. In mammals,
25 nucleotides may be synthesized through one of two
pathways: the *de novo* synthesis pathway or the salvage
pathway. The extent of utilization of each pathway is
dependent on the cell type. This selectivity has
ramifications with regard to therapeutic utility as
30 described below.

IMPDH is involved in the *de novo* synthesis of
guanosine nucleotides. IMPDH catalyzes the irreversible
NAD-dependent oxidation of inosine-5'-monophosphate
("IMP") to xanthosine-5'-monophosphate ("XMP"), Jackson
35 et al., Nature 256:331-333 (1975).

IMPDH is ubiquitous in eukaryotes, bacteria and protozoa. The prokaryotic forms share 30-40% sequence identity with the human enzyme.

Two distinct cDNA's encoding IMPDH have been identified and isolated. These transcripts are labeled type I and type II and are of identical size (514 amino acids). Collart et al., J. Biol. Chem. 263:15769-15772 (1988); Natsumeda et al., J. Biol. Chem. 265:5292-5295 (1990); and U.S. Patent 5,665,583 to Collart et al. These isoforms share 84% sequence identity. IMPDH type I and type II form tetramers in solution, the enzymatically active unit.

B and T-lymphocytes depend on the *de novo*, rather than salvage pathway, to generate sufficient levels of nucleotides necessary to initiate a proliferative response to mitogen or antigen. Due to the B and T cell's unique reliance on the *de novo* pathway, IMPDH is an attractive target for selectively inhibiting the immune system without also inhibiting the proliferation of other cells.

Immunosuppression has been achieved by inhibiting a variety of enzymes. Examples include: phosphatase calcineurin (inhibited by cyclosporin and FK-506); dihydroorotate dehydrogenase (DHODase), an enzyme involved in the biosynthesis of pyrimidines (inhibited by leflunomide and brequinar); the kinase FRAP (inhibited by rapamycin); and the heat shock protein hsp70 (inhibited by deoxyspergualin).

Inhibitors of IMPDH have also been described in the art. WO 97/40028 and U.S. Patent 5,807,876 describe a class of urea derivatives that possess a common urea backbone. WO 98/40381 describes a series of heterocyclic substituted anilines as inhibitors of IMPDH.

United States patents 5,380,879 and 5,444,072 and PCT publications WO 94/01105 and WO 94/12184 describe

mycophenolic acid ("MPA") and some of its derivatives as potent, uncompetitive, reversible inhibitors of human IMPDH type I and type II. MPA has been demonstrated to block the response of B and T-cells to mitogen or antigen. Immunosuppressants, such as MPA and derivatives of MPA, are useful drugs in the treatment of transplant rejection and autoimmune disorders, psoriasis, inflammatory diseases, including, rheumatoid arthritis, tumors and for the treatment of allograft rejection.

These are described in U.S. Pat. Nos. 4,686,234, 4,725,622, 4,727,069, 4,753,935, 4,786,637, 4,808,592, 4,861,776, 4,868,153, 4,948,793, 4,952,579, 4,959,387, 4,992,467, and 5,247,083.

The combination of agents for prevention and/or treatment of IMPDH-associated disorders, especially allograft rejection, has been investigated. In one study, it was observed that cyclic AMP agonists, such as Rolipram (Schering AG), a Type 4 Phosphodiesterase Inhibitor (PDE4) and immunomodulator, synergized with IMPDH inhibitor MPA by a cAMP- and IMPDH-dependent dependent mechanism. (P.A. Canelos, L.M. Lichtenstein, S.K. Huang, D.M. Essayan, J. Allergy and Clinical Immunology, 107:593 (2001)). The chemical structure of Rolipram is [4-[3-(cyclopentyloxy)-4-methoxy-phenyl]-2-pyrrolidinone]. The investigators found that cyclic AMP agonists, such as the PDE4 inhibitor Rolipram (Rol), markedly downregulated antigen-specific T lymphocyte responses through their effects on a variety of signaling pathways. In the study, the potential for a very low concentration of Rol (10^{-7} M, approximate IC_{10}) to synergize with a variety of immunosuppressive agents used for the prevention and/or treatment of allograft rejection was defined. While little or no synergistic effect on inhibition of antigen-induced proliferation (assessed by 3H Thymidine incorporation) could be

demonstrated with calcineurin antagonists (cyclosporine and tacrolimus), sirolimus, or corticosteroids, a marked synergistic effect was demonstrated with MPA, the active metabolite of mycophenolate mofetil (CellCept, Roche).

5 This effect was statistically significant over 4 orders of magnitude (10^{-6} to 10^{-9} M). This synergism was recapitulated with dibuteryl-cAMP (2×10^{-6} M, approximate IC_{10}) and inhibited with the use of H-9, suggesting a mechanism involving both cAMP and protein kinase A.

10 Since MPA is a selective, uncompetitive, and reversible inhibitor of IMPDH, a key enzyme in the purine salvage pathway, the potential for cAMP-mediated cross-talk at this locus was further investigated. It was found that gene expression for IMPDH types I and II
15 (assessed by RT-PCR) remained unaffected by the administration of rolipram, MPA, or both at low and high concentrations. However, functional reversal of the synergistic effect was demonstrated with the use of deoxyguanosine, a specific antagonist of MPA on IMPDH (%
20 inhibition of proliferation 81 ± 16 vs. 35 ± 12 , $p < 0.05$). Finally, despite a marked synergistic effect on inhibition of proliferation, no significant downregulation in the generation of proinflammatory cytokines (IL-2, IL-4, and IFN , each assessed by RT-
25 PCR), could be detected with the administration of Rol 10^{-7} M, MPA 10^{-8} M, or the combination. It was concluded that Rol demonstrates marked synergy with MPA by a cAMP- and IMPDH-dependent mechanism. The utility of this combination of agents for the induction of T cell
30 tolerance was suggested by the specificity of the observed effect for proliferation, without the abrogation of cytokine generation and early signaling processes.

Tiazofurin, ribavirin and mizoribine also inhibit IMPDH. These nucleoside analogs are competitive inhibitors of IMPDH; however, these agents inhibit other NAD dependent enzymes. This low level of selectivity for IMPDH limits the therapeutic application of tiazofurin, ribavirin and mizoribine. Thus, new agents which have improved selectivity for IMPDH would represent a significant improvement over the nucleoside analogs.

Mycophenolate mofetil, sold under the trade name CELLCEPT, is a prodrug which liberates MPA *in vivo*. It is approved for use in preventing acute renal allograft rejection following kidney transplantation. The side effect profile limits the therapeutic potential of this drug. MPA is rapidly metabolized to the inactive glucuronide *in vivo*. In humans, the blood levels of glucuronide exceed that of MPA. The glucuronide undergoes enterohepatic recycling causing accumulation of MPA in the bile and subsequently in the gastrointestinal tract. This together with the production of the inactive glucuronide effectively lowers the drug's *in vivo* potency, while increasing its undesirable gastrointestinal side effects.

Unlike type I, type II mRNA is preferentially upregulated in human leukemic cell lines K562 and HL-60. Weber, J. Biol. Chem. 266: 506-509 (1991). In addition, cells from human ovarian tumors and leukemic cells from patients with chronic granulocytic, lymphocytic and acute myeloid leukemias also display an up regulation type II mRNA. This disproportionate increase in IMPDH activity in malignant cells may be addressed through the use of an appropriate IMPDH inhibitor. IMPDH has also been shown to play a role in the proliferation of smooth muscle cells, indicating that inhibitors of IMPDH may be useful in preventing restenosis or other hyperproliferative vascular diseases.

IMPDH has been shown to play a role in viral replication in some viral cell lines. Carr, J. Biol. Chem. 268:27286-27290 (1993). The IMPDH inhibitor VX-497, is currently being evaluated for the treatment of hepatitis C virus in humans. Ribavirin has also been used in the treatment of hepatitis C and B viruses and when used in combination with interferon an enhancement in activity was observed. The IMPDH inhibitor ribavirin is limited by its lack of a sustained response in monotherapy and broad cellular toxicity.

There remains a need for potent selective inhibitors of IMPDH with improved pharmacological properties, physical properties and fewer side effects. Such inhibitors would have therapeutic potential as immunosuppressants, anti-cancer agents, anti-vascular hyperproliferative agents, antiinflammatory agents, antifungal agents, antipsoriatic and anti-viral agents. The compounds of the present invention are effective inhibitors of IMPDH.

"IMPDH-associated disorders" refers to any disorder or disease state in which inhibition of the enzyme IMPDH (inosine monophosphate dehydrogenase, EC1.1.1.205, of which there are presently two known isozymes referred to as IMPDH type 1 and IMPDH type 2) would modulate the activity of cells (such as lymphocytes or other cells) and thereby ameliorate or reduce the symptoms or modify the underlying cause(s) of that disorder or disease.

15 There may or may not be present in the disorder or disease an abnormality associated directly with the IMPDH enzyme. Examples of IMPDH-associated disorders include transplant rejection and autoimmune disorders, such as rheumatoid arthritis, multiple sclerosis, juvenile

20 diabetes, asthma, and inflammatory bowel disease, as well as inflammatory disorders, cancer and tumor disorders, T-cell mediated hypersensitivity diseases, ischemic or reperfusion injury, viral replication diseases, proliferative disorders and vascular diseases.

25 As used herein the term "treating" includes prophylactic and therapeutic uses, and refers to the alleviation of symptoms of a particular disorder in a patient, the improvement of an ascertainable measurement associated with a particular disorder, or the prevention

30 of a particular immune response (such as transplant rejection). The term "patient" refers to a mammal, preferably a human.

The compounds of this invention may contain one or more asymmetric carbon atoms and thus may occur as

35 racemates and racemic mixtures, single enantiomers,

diastereomeric mixtures and individual diastereomers. All such isomers of the compounds disclosed herein are expressly included within the scope of the present invention. Each stereogenic carbon may be of the R or S configuration.

Combinations of substituents and variables thereof that result in stable compounds are also contemplated within the present invention. The term "stable" as used herein refers to compounds which possess stability sufficient to allow manufacture and which maintain their integrity for a sufficient period of time to be useful as a therapeutic or diagnostic agent.

A "pharmaceutically acceptable derivative or prodrug" includes any pharmaceutically acceptable salt, ester, salt of an ester, or other derivative of a compound of the present invention which, upon administration to a subject, is capable of providing (directly or indirectly) a compound of the invention. Particularly favored derivatives and prodrugs are those that increase the bioavailability of the compounds of the present invention when such compound is administered to a subject (e.g., by allowing an orally administered compound to be more readily absorbed into the blood) or which enhance delivery of the parent compound to a biological compartment (e.g., the brain or lymphatic system) relative to the parent species. Preferred prodrugs include derivatives where a group that enhances aqueous solubility or active transport through the gut membrane is appended to a compound of the present invention.

Pharmaceutically acceptable salts of the compounds disclosed herein include those derived from pharmaceutically acceptable inorganic and organic acids

and bases known to those skilled in the art. Examples of suitable acid salts include, but are not limited to, the following: acetate, adipate, alginate, aspartate, benzoate, benzenesulfonate, bisulfate, butyrate, citrate, camphorate, camphorsulfonate, cyclopentanepropionate, digluconate, dodecylsulfate, ethanesulfonate, formate, fumarate, glucoheptanoate, glycerophosphate, glycolate, hemisulfate, heptanoate, hexanoate, hydrochloride, hydrobromide, hydroiodide, 2-hydroxyethanesulfonate, lactate, maleate, malonate, methanesulfonate, 2-naphthalenesulfonate, nicotinate, nitrate, oxalate, palmoate, pectinate, persulfate, 3-phenylpropionate, phosphate, picrate, pivalate, propionate, salicylate, succinate, sulfate, tartrate, thiocyanate, trifluoroacetic, tosylate and undecanoate. Other acids, for example oxalic, while not in themselves pharmaceutically acceptable, may be employed in the preparation of salts useful as intermediates in obtaining the compounds of the present invention and their pharmaceutically acceptable acid additional salts.

Salts derived from appropriate bases include, but are not limited to, the following: alkali metal (e.g., sodium), alkaline earth metal (e.g., magnesium), ammonium and $N-(C_{1-4} \text{ alkyl})_4^+$ salts. The present invention also envisions the quaternization of any basic nitrogen-containing groups of the compounds disclosed herein. Water- or oil-soluble or dispersible products may be obtained by such quaternization.

Methods of Preparation

The compounds of the present invention may be synthesized using conventional techniques known in the art. Advantageously, these compounds are conveniently

synthesized from readily available starting materials. Following are general synthetic schemes for manufacturing compounds of the present invention. These schemes are illustrative and are not meant to limit the possible techniques one skilled in the art may use to manufacture compounds disclosed herein. Different methods will be evident to those skilled in the art. Additionally, the various steps in the synthesis may be performed in an alternate sequence or order to give the desired compound(s). All documents cited herein are incorporated herein by reference in their entirety.

Compounds of the present invention can be made by many methods, which will be known to one skilled in the art of organic chemistry. In general, the time taken to complete a reaction procedure will be judged by the person performing the procedure, preferably with the aid of information obtained by monitoring the reaction by methods such as HPLC or TLC. A reaction does not have to go to completion to be useful to this invention. The preparation of heterocycles useful to this invention are described in the series of books: "Comprehensive Heterocyclic Chemistry, The Structure, Reactions, Synthesis and Uses, of Heterocyclic Compounds" Katritzky, A.R., Rees, C.W. Eds Pergamon Press New York, First edition 1984, and "Comprehensive Heterocyclic Chemistry II, A Review of the Literature 1982-1995. The Structure, Reactions, Synthesis and Uses, of Heterocyclic Compounds" Katritzky, A.R., Rees, C.W. and Scriven, E., F. Eds Pergamon Press New York, 1996.

Amines such as anilines or heterocyclic amines, useful for the preparation of compounds useful to this invention may be commercially available or readily prepared by many methods known to one skilled in the art of organic chemistry, and are described in "Comprehensive Organic Transformations A Guide to

Functional Group Preparation" pp 385-439. Richard C. Larock 1989 VCH Publishers, Inc. Examples include but are not limited to reduction of a nitro group, and reduction of an azide. Methods for the production of amines useful to this invention are outlined in Schemes 1a-1f.

A general method for the synthesis of the anilines such as (1a.4) useful in this invention can be performed by metal catalyzed cross coupling methods known in the literature. The simplest case is a Suzuki type cross coupling (Miyaura, N., Yanagi, T. Suzuki, A., Synth. Comm. 11(7):513-519 (1981); A. Suzuki et. al., J. Am. Chem. Soc. 111:513 (1989); and V. N. Kalinin, Russ. Chem. Rev. 60:173 (1991)) of an aryl boronic acid or ester (1a.1) (as shown below) with an appropriate bromoheterocycle in the presence of a suitable catalyst such as tetrakis (triphenylphosphine) palladium. After the cross coupling has been performed the product may be deprotected. The choice of protecting group and its method of removal will be readily apparent to one skilled in the art of organic chemistry. Such considerations and methods are, for example, described by Greene, Theodora W. and Wuts, Peter G. M. in "Protective Groups in Organic Synthesis." 2nd Ed., (1991) Publisher: (John Wiley and Sons, Inc., New York, N.Y. For example, if the protecting group is acetyl the product may be deprotected by treatment with aqueous potassium hydroxide at a concentration of 0.5N to 5 N at room temperature to 100 °C for a period between 0.5h and 24h.

For example aryl boronic acid (1a.5) may react with the known 5-bromothiazole (1a.6) in the presence of tetrakis(triphenylphosphine) palladium (0), to provide (1a.7) which may be deprotected by an appropriate method.

Scheme 1a

Copper has been recently been shown to be an effective catalyst for cross coupling of aryl boronic acids to N-unsubstituted heterocycles as described by Chan et al., Tetrahed. Lett. 39:2933-2936 (1998); and Lam et al., Tetrahed. Lett. 39:2941-2944 (1998). This results in compounds in which the heterocycle is attached to the aryl ring through nitrogen rather than carbon.

For example aryl boronic acid (1a.5) may react with oxazolone (1a.8) in the presence of copper (II) acetate in the presence of an amine base such as pyridine to provide intermediate (1a.9) which may be deprotected by an appropriate method

In general aryl boronic acids and esters, 1b.3, where X is not Br or I, may be prepared as shown in

Scheme Ib, from the corresponding arylbromide (1b.1) by treatment with a palladium catalyst such as [1,1'-Bis(diphenylphosphino)-ferrocene] dichloropalladium (II) and bis(pinacolato)diboron, (1b.2), as reported by

5 Ishayama et al., J. Org. Chem., (1995) 7508-7510. Aryl boronic esters may be converted to the corresponding boronic acid by several methods including treatment with aqueous HCl. In a variation of the synthesis, the

10 nitrogen may be masked as a nitro group and later reduced by several means including metal reductions, such as by treatment with tin chloride in HCl or by refluxing the nitro compound with zinc in the presence of CaCl₂ in a solvent such as ethanol, or in certain cases the nitro group may be reduced by catalytic hydrogenation in the

15 presence of catalysts such as palladium on carbon. The conditions for the reduction of nitro groups are detailed in several references including Hudlicky, M., "Reductions in Organic Chemistry", 2nd Ed., ACS Monograph 188, 1996, pp 91-101, American Chemical Society, Washington, DC. A

20 second variation of the synthesis allows the aryl bromide to remain through the entire synthesis and elaborated to the boronic acid at the end. This may eliminate the need for a protecting group.

In certain cases it may be more expedient to construct the heterocyclic ring by other methods. A general method for the synthesis of 5-membered

heterocycles includes the 1,3-dipolar cycloaddition reaction, which is well known to one skilled in the art of organic chemistry and is described by Padwa, Albert, Editor in "1,3-Dipolar Cycloaddition Chemistry, Vol. 2" (1984) John Wiley and Sons, New York, N. Y.; and Padwa, Albert; Editor. in "1,3-Dipolar Cycloaddition Chemistry, Vol. 1" (1984) John Wiley and Sons, New York, N. Y. For example oxazoles may be prepared by 1,3 dipolar cycloaddition of the corresponding aldehyde (1c.1) and (p-tolylsulfonyl)methyl isocyanate (TOSMIC) (1c.2) as shown in scheme 1c. The aldehyde may be commercially available or prepared from the corresponding methyl group by oxidation with reagents such as CrO_3 , MnO_2 , and ammonium cerium (IV) nitrate by methods well known to one skilled in the art of organic chemistry and is described in Hudlicky, M., "Oxidations in Organic Chemistry", ACS Monograph 186 (1990), American Chemical Society, Washington, DC. The nitro group in intermediate (1c.3), is reduced to an amine (1c.4), as discussed above.

20

Scheme 1c

An alternative method of producing amines useful to this invention is by nucleophilic attack on an electron deficient ring system as outlined in Scheme 1d.

5 Halonitrobenzenes (1d.1), are either commercially available or readily prepared by methods known to one skilled in the art of organic synthesis. Displacement with a variety of nucleophiles produce compounds of structure (1d.2). In one example heating (1d.3) with a nucleophilic heterocycle such as triazole with or without the addition of a base provides the intermediate nitro compound which may be reduced as previously described to provide amines (1d.4). Alternatively simple organic

10

15 nucleophiles such as cyanide can be reacted with halonitrobenzene (1d.5) to provide an intermediate nitrocompound which can be reduced by many methods to an amine (1d.6).

Scheme 1d

In some cases it will be useful to have an ortho-bromo or ortho-iodo aniline as an intermediate for the synthesis of heterocycles useful for this invention as described in scheme 1e. Bromination of anilines may be accomplished in many cases by simply dissolving the aniline, such as (1a.4) and (1c.4), in a suitable solvent such as methylene chloride, chloroform, acetic acid or hydrochloric acid, and treating with one equivalent of bromine, at a temperature from -78 to 40°C to provide aniline (1e.1 and 1e.2). In some cases the aniline may be protected with a group such as acetate. In this case the bromination can often be accomplished by the addition of a Lewis acid catalyst such as iron, or FeBr_3 . Iodination can be effected in a manner analogous to that described for bromine, but may also benefit from the addition of silver salts such as silver benzoate, silver triflate, silver trifluoroacetate, or periodic acid, to provide aniline (1e.3) and (1e.4).

Scheme 1e

5 The synthesis of useful aniline intermediates which contain an ortho keto group (1f.3) is depicted in Scheme 1f. They may be prepared from anilines (1e.1) and (1e.2, shown) by palladium mediated coupling with an appropriate alkoxyvinyl stannane (1f.1) to produce the enol-ether (1f.2). Hydrolysis of the enol-ether with dilute acid provides the ketone (1f.3)

Scheme 1f

In the case where the compounds useful; for this invention are quinolines they may be conveniently prepared from the corresponding anilines via several methods including those outlined in Scheme 2a, through 2c.

In scheme 2a, aniline (2a.1), (of which anilines (1a.4) and (1c.4) are examples) is heated in an inert solvent such as toluene, xylene, or diphenylether at a temperature up to the boiling point of the solvent with a β -ketoester (2a.2) to provide quinolone (2a.3). This method of quinolone synthesis has been described in the literature, for example see Kuo et al. in J. Med. Chem 1993, 36, 1146-1156. In some cases this cyclization can be aided by the use of an acid such as polyphosphoric acid or sulfuric acid to facilitate the intramolecular Friedel-Crafts acylation. In some cases isomeric cyclization products may be formed. In general these may be separated by flash column chromatography or high performance liquid chromatography.

A modification of the above the synthesis has been reported by Toda, J. et al. in Heterocycles 1994, 38, 2091-2097. In this method the beta keto ester (2a.2) is converted to an enamine (2a.4) by refluxing with an

amine such as methylamine in an alcoholic solvent in the presence of acetic acid. The enamine (2a.4) is then reacted with an aniline such as (2a.1) in an inert solvent such as benzene, methylene chloride, or carbon tetrachloride in the presence of an equivalent of pyridinium p-toluenesulfonate (PPTS) to effect an N-N exchange reaction to produce enamine (2a.5). This can be cyclized to the quinolone by heating in an inert solvent such as xylene at a temperature between 150-300°C. In some cases, as mentioned above, an acid catalyst may be added to aid in the intramolecular Friedel-Crafts acylation.

Scheme 2a

15

β -ketoesters such as (IIa.2) useful for this invention are either commercially available or readily

prepared from the corresponding carboxylic acids or esters by several means including, that reported by Clay, R.J., et al., in Synthesis, 1993, 290-292, and those outlined in chapter 2 of "Advanced Organic Chemistry" 3rd edition (1990) by Carey, F. A., and Sundberg R. J., Plenum Press, New York, N. Y.

An alternative quinolone synthesis starting from aniline (1e.3) (of which aniline 1e.4 is an example) is depicted in Scheme 2b. This method of quinolone synthesis has been described in the literature, for example see Kalinin, V.N., et. al. Tetrahedron Lett. 1992, 33, 373-376, and Torii, S., et. al. in Tetrahedron 1993, 42, 6773-6784. The aniline (1e.3) is heated between 60-160°C in the presence of an acetylene (2d.1) and 0.1- 5 mol% of a palladium catalyst such as tetrakis(triphenylphosphine) palladium (0), dichlorobis (triphenylphosphine)palladium (II), or dichloro[1,1'-bis(diphenylphosphino)ferrocene palladium(II), in an atmosphere of carbon monoxide (3-40 atmospheres) in a steel autoclave.

Scheme 2b

Acetylenes 2d.1 are either commercially available or may be prepared by several methods including, palladium catalyzed coupling with an aryl or vinyl bromide or iodide with trimethylsilylacetylene as initially described by Takahashi, S. et. al. in Synthesis 1980, 627. The trimethylsilyl protecting group may be removed by treatment with aqueous base or with a fluoride source such as tetrabutylammonium fluoride. An alternative synthesis of terminal acetylenes is commonly known as the

Corey-Fuchs sythesis, for examples see Wang,Z. et al. J.Org. Chem.2000, 65, 1889 - 91, and references contained therein. The Corey-Fuchs syntheses and its modifications start with an appropriately substituted aldehyde. The aldehydes useful for this invention are either commercially available or readily prepared by oxidation of an alcohol by many methods as described by Hudlicky, M. "Oxidations in Organic Chemistry", ACS Monograph 186, 1990, American Chemical Society, Washington, DC.

Another alternative synthesis of quinolones has been reported in the literature for example see, Li, L., et al. in J. Med. Chem. 1994, 37, 3400-3407, and is depicted in Scheme 2c. Aniline (1f.3) is coupled with an carboxylic acid (2c.1) to form an amide (2c.2). The coupling is carried out using any of the many methods for the formation of amide bonds known to one skilled in the art of organic synthesis. These methods include but are not limited to conversion of the acid to the corresponding acid chloride, or use of standard coupling procedures such as the azide method, mixed carbonic acid anhydride (isobutyl chloroformate) method, carbodiimide (dicyclohexylcarbodiimide, diisopropylcarbodiimide, or water-soluble carbodiimides) method, active ester (p-nitrophenyl ester, N-hydroxysuccinic imido ester) method, carbonyldiimidazole method, phosphorus reagents such as BOP-Cl. Some of these methods (especially the carbodiimide) can be enhanced by the addition of 1-hydroxybenzotriazole. The amide (2c.2) is then treated with a base such as potassium tert-butoxide to effect cyclization to the quinolone (2c.3).

Chem Research **1995**, 164-165.

Acids (2c.1) useful for this invention in their own right or for the preparation of beta ketoesters such as (2a.2) are either commercially available or readily prepared by a number of methods known to one skilled in the art of organic chemistry including, oxidation of an alcohol or hydrolysis of an ester. Transformations that produce acids from commercially available reagents are described by Larock, R.C. in "Comprehensive Organic Transformations: a Guide to Functional Group Preparations." 1989, VCH Publishers, N.Y., N.Y..

Activity of IMPDH I and IMPDH II was measured following an adaptation of the method described in WO 97/40028. The reaction mixture was prepared containing 0.1M Tris pH 8.0, 0.1 M KCl, 3 mM EDTA, 2 mM DTT, 0.4 mM IMP and 40 nM enzyme (IMPDH I or IMPDH II). The reaction was started by the addition of NAD to a final concentration of 0.4 mM. The enzymatic reaction was followed by measuring the increase in absorbance at 340 nM that results from the formation of NADH. For the analysis of potential inhibitors of the enzyme, compounds were dissolved in DMSO to a final concentration of 10 mM and added to the assay mixture such that the final concentration of DMSO was 2.5%. The assay was carried out in a 96-well plate format, with a final reaction volume of 200 μ l.

The compounds disclosed herein are capable of inhibiting the enzyme IMPDH at a measurable level, under the above-described assay or an assay which can determine an effect of inhibition of the enzyme IMPDH.

Example 17-Methoxy-6-(5-oxazolyl)-2-phenyl-4(1H)-quinolinone**1**Example 1 Part A, 4-Nitro-2-methoxy-(α,α -bisacetoxy)toluene**1A**

To a 5 L three necked round bottom flask equipped with a mechanical stirrer was added 4-nitro-2-methoxytoluene (150.0 g, 0.8973 mol), HOAc (900 mL) and Ac₂O (900 mL). The mixture was stirred and cooled to 8° C with an acetone/ice bath. Concentrated H₂SO₄ (136 mL) was carefully added while keeping the reaction temperature below 19 °C. After cooling to 0 °C, CrO₃ (252.6 g, 2.526 mol, 2.815 equiv.) was added portion-wise over 1 hour while maintaining the reaction temperature between 0-10 °C. After the addition, the mixture was stirred at 0 °C for 30 minutes at which time the reaction was complete. The reaction mixture was then carefully poured into ice (1.5 kg) with stirring to give a slurry. The remaining black gummy residue was rinsed with HOAc (3 x 100 mL), and the washes were added to the slurry. After stirring for 10 minutes, the slurry was filtered. The cake was washed with water (3 x 400 mL) and suction dried for 17 hours to **1A** (129.0 g, 51%). ¹H NMR (CDCl₃) δ 8.02 (s, 1H), 7.89 (d, J = 8.4 Hz, 1H), 7.77 (s, 1H), (d, 8.4 Hz, 1H), 3.98 (s, 3H), 2.16 (s, 6H).

To a solution of 6-bromoindanol (0.65 g, 3.02 mmol) in toluene (10 mL) was added thionyl chloride (0.34 mL, 4.53 mmol) and the contents heated at 50 °C for one hour. The reaction mixture was cooled to room temperature and partitioned between dichloromethane (20 mL) and water (20 mL). The dichloromethane layer was dried over sodium sulfate and concentrated under reduced pressure to yield a liquid (0.63 g) which was used as such for the subsequent step without further purification.

To 6-bromo-1-chloroindane obtained in the previous step was added methylamine (6 mL of a 33% solution in ethanol) and the contents heated in a sealed tube at 90 °C for eighteen hours. The reaction mixture was concentrated under reduced pressure and purified by silica gel flash chromatography using dichloromethane/methanol to yield the title compound (0.251 g, 37%). ¹H NMR (CDCl₃): δ 7.45 (s, 1H), 7.25 (d, 1H), 7.0 (d, 1H), 4.1 (t, 1H), 2.9 (m, 1H), 2.7 (m, 1H), 2.5 (brs, 1H), 2.4 (s, 3H), 2.3 (m, 1H), 1.8 (m, 1H).
